

DESCRIPTION

- The LTC®4274 is a single power sourcing equipment controller designed for use in IEEE 802.3 Type 1 and Type 2 (high power) compliant Power over Ethernet systems. External power MOSFETs enhance system reliability and minimize channel resistance, cutting power dissipation and eliminating the need for heatsinks even at Type 2 power levels. External power components also allow use at very high power levels while remaining otherwise compatible with the IEEE standard. 80V-rated port pins provide robust protection against external faults.

The LTC4274 includes advanced power management features, including current and voltage readback and programmable I_{CUT} and I_{LIM} thresholds. Available C libraries simplify software development; an optional AUTO pin mode provides fully IEEE-compliant standalone operation with no software required. Proprietary 4-point PD detection circuitry minimizes false PD detection while supporting legacy phone operation. Midspan operation is supported with built-in 2-event classification and backoff timing. Host communication is via a 1MHz ^2C serial interface.

The LTC4274 is available in a 5mm × 7mm QFN package that significantly reduces board space compared with competing solutions.

APPLICATIONS

- PSE Switches/Routers
- PSE Midspans

LT, LTIC, LTM, Linear Technology and the Linear logo are registered trademarks and ThinSOT is a trademark of Linear Technology Corporation. All other trademarks are the property of their respective owners.

TYPICAL APPLICATION

Complete Ethernet High Power Source

LTC4274

ABSOLUTE MAXIMUM RATINGS

Supply Voltages (Note 1)

AGND – V_{EE} –0.3V to 80V

DGND – V_{EE} –0.3V to 80V

V_{DD} – DGND –0.3V to 5.5V

Digital Pins

SCL, SDAIN, SDAOUT, \overline{INT} , \overline{SHDN} , \overline{MSD} , ADn,

RESET, AUTO, MID DGND –0.3V to V_{DD} + 0.3V

Analog Pins

GATE, SENSE, OUT V_{EE} –0.3V to V_{EE} + 80V

Operating Temperature Range

LTC4274C 0°C to 70°C

LTC4274I –40°C to 85°C

Junction Temperature (Note 2) 125°C

Storage Temperature Range –65°C to 150°C

Lead Temperature (Soldering, 10 sec) 300°C

PIN CONFIGURATION

ORDER INFORMATION

LEAD FREE FINISH	TAPE AND REEL	PART MARKING*	PACKAGE DESCRIPTION	TEMPERATURE RANGE
LTC4274CUHF#PBF	LTC4274CUHF#TRPBF	4274	38-Lead (5mm × 7mm) Plastic QFN	0°C to 70°C
LTC4274IUHF#PBF	LTC4274IUHF#TRPBF	4274	38-Lead (5mm × 7mm) Plastic QFN	–40°C to 85°C

Consult LTC Marketing for parts specified with wider operating temperature ranges. *The temperature grade is identified by a label on the shipping container. Consult LTC Marketing for information on non-standard lead based finish parts.

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: This IC includes overtemperature protection that is intended to protect the device during momentary overload conditions. Junction temperature will exceed 140°C when overtemperature protection is active. Continuous operation above the specified maximum operating junction temperature may impair device reliability.

Note 3: All currents into device pins are positive; all currents out of device pins are negative.

Note 4: The LTC4274 operates with a negative supply voltage (with respect to ground). To avoid confusion, voltages in this data sheet are referred to in terms of absolute magnitude.

Note 5: t_{DIS} is the same as t_{MPDO} defined by IEEE 802.3at.

Note 6: The LTC4274 digital interface operates with respect to DGND. All logic levels are measured with respect to DGND.

Note 7: Guaranteed by design, not subject to test.

Note 8: The IEEE 802.3af specification allows a PD to present its Maintain Power Signature (MPS) on an intermittent basis without being disconnected. In order to stay powered, the PD must present the MPS for t_{MPS} within any t_{MPDO} time window.

Note 9: Values measured at $V_{\text{ILD}}(\text{MAX})$ and $V_{\text{IHD}}(\text{MIN})$.

Note 10: If fault condition occurs during an I²C transaction, the $\overline{\text{INT}}$ pin will not be pulled down until a stop condition is present on the I²C bus.

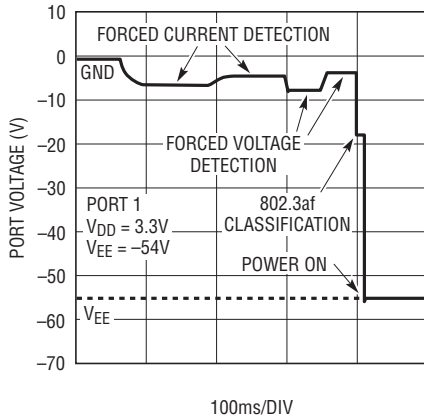

Note 11: Load Characteristic of the LTC4274 during Mark:

$$7\text{V} < (\text{AGND} - V_{\text{OUT}}) < 10\text{V} \text{ or } I_{\text{OUT}} < 50\mu\text{A}$$

Note 12: See the LTC4274 Software Programming documentation for information on serial bus usage and device configuration and status registers.

Figure 7. Reading from a Register

Figure 8. Reading the Interrupt Register (Short Form)

Figure 9. Reading from Alert Response Address

PIN FUNCTIONS

RESET: Chip Reset, Active Low. When the $\overline{\text{RESET}}$ pin is low, the LTC4274 is held inactive with all ports off and all internal registers reset to their power-up states. When $\overline{\text{RESET}}$ is pulled high, the LTC4274 begins normal operation. $\overline{\text{RESET}}$ can be connected to an external capacitor or RC network to provide a power turn-on delay. Internal filtering of the $\overline{\text{RESET}}$ pin prevents glitches less than 1 μ s wide from resetting the LTC4274. Internally pulled up to V_{DD} .

MID: Midspan Mode Input. When high, the LTC4274 acts as a midspan device. Internally pulled down to DGND.

INT: Interrupt Output, Open Drain. $\overline{\text{INT}}$ will pull low when any one of several events occur in the LTC4274. It will return to a high impedance state when bits 6 or 7 are set in the Reset PB register (1Ah). The $\overline{\text{INT}}$ signal can be used to generate an interrupt to the host processor, eliminating the need for continuous software polling. Individual $\overline{\text{INT}}$ events can be disabled using the Int Mask register (01h). See the LTC4274 Software Programming documentation for more information. The $\overline{\text{INT}}$ pin is only updated between I²C transactions.

SCL: Serial Clock Input. High impedance clock input for the I²C serial interface bus. SCL must be tied high if not used.

SDAOUT: Serial Data Output, Open Drain Data Output for the I²C Serial Interface Bus. The LTC4274 uses two pins to implement the bidirectional SDA function to simplify optoisolation of the I²C bus. To implement a standard bidirectional SDA pin, tie SDAOUT and SDAIN together. SDAOUT should be grounded or left floating if not used. See Applications Information for more information.

SDAIN: Serial Data Input. High impedance data input for the I²C serial interface bus. The LTC4274 uses two pins to implement the bidirectional SDA function to simplify optoisolation of the I²C bus. To implement a standard bidirectional SDA pin, tie SDAOUT and SDAIN together. SDAIN must be tied high if not used. See Applications Information for more information.

AD3: Address Bit 3. Tie the address pins high or low to set the I²C serial address to which the LTC4274 responds. This address will be 010A₃A₂A₁A₀b. Internally pulled up to V_{DD} .

AD2: Address Bit 2. See AD3.

AD1: Address Bit 1. See AD3.

AD0: Address Bit 0. See AD3.

NC, DNC: All pins identified with “NC” or “DNC” must be left unconnected.

DGND: Digital Ground. DGND is the return for the V_{DD} supply.

V_{DD} : Logic Power Supply. Connect to a 3.3V power supply relative to DGND. V_{DD} must be bypassed to DGND near the LTC4274 with at least a 0.1 μ F capacitor.

SHDN: Shutdown, Active Low. When pulled low, $\overline{\text{SHDN}}$ shuts down the port, regardless of the state of the internal registers. Pulling $\overline{\text{SHDN}}$ low is equivalent to setting the Reset Port bit in the Reset Pushbutton register (1Ah). Internal filtering of the $\overline{\text{SHDN}}$ pin prevents glitches less than 1 μ s wide from resetting the port. Internally pulled up to V_{DD} .

AGND: Analog Ground. AGND is the return for the V_{EE} supply.

SENSE: Current Sense Input. SENSE monitors the external MOSFET current via a 0.5 Ω or 0.25 Ω sense resistor between SENSE and V_{EE} . Whenever the voltage across the sense resistor exceeds the overcurrent detection threshold V_{CUT} , the current limit fault timer counts up. If the voltage across the sense resistor reaches the current limit threshold V_{LIM} , the GATE pin voltage is lowered to maintain constant current in the external MOSFET. See Applications Information for further details.

GATE: Gate Drive. GATE should be connected to the gate of the external MOSFET for the port. When the MOSFET is turned on, the gate voltage is driven to 13V (typ) above V_{EE} . During a current limit condition, the voltage at GATE will be reduced to maintain constant current through the external MOSFET. If the fault timer expires, GATE is pulled down, turning the MOSFET off and recording a t_{CUT} or t_{START} event.

PIN FUNCTIONS

OUT: Output Voltage Monitor. OUT should be connected to the output port. A current limit foldback circuit limits the power dissipation in the external MOSFET by reducing the current limit threshold when the drain-to-source voltage exceeds 10V. The Power Good bit is set when the voltage from OUT to V_{EE} drops below 2.4V (typ). A 500k resistor is connected internally from OUT to AGND when the port is idle.

V_{EE} : Main Supply Input. Connect to a $-45V$ to $-57V$ supply, relative to AGND.

AUTO: AUTO Pin Mode Input. AUTO pin mode allows the LTC4274 to detect and power up a PD even if there is no host controller present on the I²C bus. The voltage of the

AUTO pin determines the state of the internal registers when the LTC4274 is reset or comes out of V_{DD} UVLO (see the Register map). The states of these register bits can subsequently be changed via the I²C interface. The real-time state of the AUTO pin is read at bit 0 in the Pin Status register (11h). Internally pulled down to DGND. Must be tied locally to either V_{DD} or DGND.

\overline{MSD} : Maskable Shutdown Input. Active low. When pulled low, all ports that have their corresponding mask bit set in the Misc Config register (17h) will be reset, equivalent to pulling the \overline{SHDN} pin low. Internal filtering of the \overline{MSD} pin prevents glitches less than 1 μ s wide from resetting ports. Internally pulled up to V_{DD} .

OPERATION

Overview

Power over Ethernet, or PoE, is a standard protocol for sending DC power over copper Ethernet data wiring. The IEEE group that administers the 802.3 Ethernet data standards added PoE powering capability in 2003. This original PoE spec, known as 802.3af, allowed for 48V DC power at up to 13W. This initial spec was widely popular, but 13W was not adequate for some requirements. In 2009, the IEEE released a new standard, known as 802.3at or PoE+, increasing the voltage and current requirements to provide 25W of power.

The IEEE standard also defines PoE terminology. A device that provides power to the network is known as a PSE, or power sourcing equipment, while a device that draws power from the network is known as a PD, or powered device. PSEs come in two types: Endpoints (typically network switches or routers), which provide data and power; and Midspans, which provide power but pass through data. Midspans are typically used to add PoE capability to existing non-PoE networks. PDs are typically IP phones, wireless access points, security cameras, and similar devices, but could be nearly anything that runs from 25W or less and includes an RJ45-style network connector.

The LTC4274 is a third-generation single PSE controller in either an endpoint or midspan design. Virtually all necessary circuitry is included to implement a IEEE 802.3at compliant PSE design, requiring only an external power MOSFET and sense resistor; these minimize power loss

compared to alternative designs with on-board MOSFETs and increase system reliability in the event a single channel is damaged.

PoE Basics

Common Ethernet data connections consist of two or four twisted pairs of copper wire (commonly known as CAT-5 cable), transformer-coupled at each end to avoid ground loops. PoE systems take advantage of this coupling arrangement by applying voltage between the center-taps of the data transformers to transmit power from the PSE to the PD without affecting data transmission. Figure 10 shows a high-level PoE system schematic.

To avoid damaging legacy data equipment that does not expect to see DC voltage, the PoE spec defines a protocol that determines when the PSE may apply and remove power. Valid PDs are required to have a specific 25k Ω common-mode resistance at their input. When such a PD is connected to the cable, the PSE detects this signature resistance and turns on the power. When the PD is later disconnected, the PSE senses the open circuit and turns power off. The PSE also turns off power in the event of a current fault or short circuit.

When a PD is detected, the PSE optionally looks for a classification signature that tells the PSE the maximum power the PD will draw. The PSE can use this information to allocate power among several ports, police the current consumption of the PD, or to reject a PD that will draw

Figure 10. Power Over Ethernet System Diagram

OPERATION

more power than the PSE has available. The classification step is optional; if a PSE chooses not to classify a PD, it must assume that the PD is a 13W (full 802.3af power) device.

New in 802.3at

The newer 802.3at standard supersedes 802.3af and brings several new features:

- A PD may draw as much as 25.5W. Such PDs (and the PSEs that support them) are known as Type 2. Older 13W 802.3af equipment is classified as Type 1. Type 1 PDs will work with all PSEs; Type 2 PDs may require Type 2 PSEs to work properly. The LTC4274 is designed to work in both Type 1 and Type 2 PSE designs, and also supports non-standard configurations at higher power levels.
- The Classification protocol is expanded to allow Type 2 PSEs to detect Type 2 PDs, and to allow Type 2 PDs to determine if they are connected to a Type 2 PSE. Two versions of the new Classification protocol are available: an expanded version of the 802.3af Class Pulse protocol, and an alternate method integrated with the existing LLDP protocol (using the Ethernet data path). The LTC4274 fully supports the new Class Pulse protocol and is also compatible with the LLDP protocol (which is implemented in the data communications layer, not in the PoE circuitry).
- Fault protection current levels and timing are adjusted to reduce peak power in the MOSFET during a fault; this allows the new 25.5W power levels to be reached using the same MOSFETs as older 13W designs.

BACKWARDS COMPATIBILITY

The LTC4274 is fully software and pin compatible with the LTC4266 if only port 1 was used.

The LTC4274 is designed to be backward compatible with earlier PSE chips in both software and pin functions. Existing systems using either the LTC4258 or LTC4259A (or

compatible) devices can be substituted with the LTC4274 without software or PCB layout changes if only port 1 was used; only minor BOM changes are required to implement a fully compliant 802.3at design.

Because of the backwards compatibility features, some of the internal registers are redundant or unused when the LTC4274 is operated as recommended. For more details on usage in compatibility mode, refer to the LTC4258/LTC4259A device datasheets.

Special Compatibility Mode Notes

- The LTC4274 can use either 0.5Ω or 0.25Ω sense resistors, while the LTC425x chips always used 0.5Ω. To maintain compatibility, if the AUTO pin is low when the LTC4274 powers up it assumes the sense resistor is 0.5Ω; if it is high at power up, the LTC4274 assumes 0.25Ω. The resistor value setting can be reconfigured at any time after power up. In particular, systems that use 0.25Ω sense resistors and have AUTO tied low must reconfigure the resistor settings after power up.
- The LTC4259A included both AC and DC disconnect sensing circuitry, but the LTC4274 has only DC disconnect sensing. For the sake of compatibility, register bits used to enable AC disconnect in the LTC4259A are implemented in the LTC4274, but they simply mirror the bits used for DC disconnect.
- The LTC4258 and LTC4259A required 10k resistors between the OUTn pins and the drains of the external MOSFETs. These resistors must be shorted or replaced with zero ohm jumpers when using the LTC4274.
- The LTC4258 and LTC4259A included a BYP pin, decoupled to AGND with 0.1μF. This pin changes to the MID pin on the LTC4274. The capacitor should be removed for Endspan applications, or replaced with a zero ohm jumper for Midspan applications.

APPLICATIONS INFORMATION

Operating Modes

The LTC4274 can operate in one of four modes: manual, semi-auto, AUTO pin, or shutdown.

Table 1. Operating Modes

MODE	AUTO PIN	OPMD	DETECT/ CLASS	POWER-UP	AUTOMATIC $I_{\text{CUT}}/I_{\text{LIM}}$ ASSIGNMENT
AUTO Pin	1	11b	Enabled at Reset	Automatically	Yes
Reserved	0	11b	N/A	N/A	N/A
Semi-auto	0	10b	Host Enabled	Upon Request	No
Manual	0	01b	Once Upon Request	Upon Request	No
Shutdown	0	00b	Disabled	Disabled	No

- In manual mode, the port waits for instructions from the host system before taking any action. It runs a single detection or classification cycle when commanded to by the host, and reports the result in its Port Status register. The host system can command the port to turn on or off the power at any time. This mode should only be used for diagnostic and test purposes.
- In semi-auto mode, the port repeatedly attempts to detect and classify any PD attached to it. It reports the status of these attempts back to the host, and waits for a command from the host before turning on power to the port. The host must enable detection (and optionally classification) for the port before detection will start.
- AUTO pin mode operates the same as semi-auto mode except that it will automatically turn on the power to the port if detection is successful. In AUTO pin mode, I_{CUT} and I_{LIM} values are set automatically by the LTC4274. The AUTO pin must be high at reset to ensure proper AUTO pin mode operation.
- In shutdown mode, the port is disabled and will not detect or power a PD.

Regardless of which mode it is in, the LTC4274 will remove power automatically from a port that generates a current limit fault. It will also automatically remove power from a port that generates a disconnect event if disconnect detection is enabled. The host controller may also command the port to remove power at any time.

Reset and the AUTO/MID pins

The initial LTC4274 configuration depends on the state of the AUTO and MID pins during reset. Reset occurs at power-up, or whenever the RESET pin is pulled low or the global Reset All bit is set. Note that the AUTO pin is only sampled when a reset occurs. Changing the state of AUTO or MID after power-up will not change the port behavior of the LTC4274 until a reset occurs.

Although typically used with a host controller, the LTC4274 can also be used in a standalone mode with no connection to the serial interface. If there is no host present, the AUTO pin should be tied high so that, at reset, the port will be configured to operate automatically. The port will detect and classify repeatedly until a PD is discovered, set I_{CUT} and I_{LIM} according to the classification results, apply power after successful detection, and remove power when a PD is disconnected. Similarly, if the standalone application is a midspan, the MID pin should be tied high to enable correct midspan detection timing.

Table 2 shows the I_{CUT} and I_{LIM} values that will be automatically set in AUTO pin mode, based on the discovered class.

Table 2. I_{CUT} and I_{LIM} Values in AUTO Pin Mode

CLASS	I_{CUT}	I_{LIM}
Class 1	112mA	425mA
Class 2	206mA	425mA
Class 3 or Class 0	375mA	425mA
Class 4	638mA	850mA

The automatic setting of the I_{CUT} and I_{LIM} values only occurs if the LTC4274 is reset with the AUTO pin high.

APPLICATIONS INFORMATION

DETECTION

Detection Overview

To avoid damaging network devices that were not designed to tolerate DC voltage, a PSE must determine whether the connected device is a real PD before applying power. The IEEE specification requires that a valid PD have a common-mode resistance of $25k \pm 5\%$ at any port voltage below 10V. The PSE must accept resistances that fall between 19k and 26.5k, and it must reject resistances above 33k or below 15k (shaded regions in Figure 11). The PSE may choose to accept or reject resistances in the undefined areas between the must-accept and must-reject ranges. In particular, the PSE must reject standard computer network ports, many of which have 150Ω common-mode termination resistors that will be damaged if power is applied to them (the black region at the left of Figure 11).

Figure 11. IEEE 802.3af Signature Resistance Ranges

4-Point Detection

The LTC4274 uses a 4-point detection method to discover PDs. False-positive detections are minimized by checking for signature resistance with both forced-current and forced-voltage measurements. Initially, two test currents are forced onto the port (via the OUT pin) and the resulting voltages are measured. The detection circuitry subtracts the two V-I points to determine the resistive slope while removing offset caused by series diodes or leakage at the port (see Figure 12). If the forced-current detection yields a valid signature resistance, two test voltages are then forced onto the port and the resulting currents are measured and subtracted. Both methods must report valid resistances for the port to report a valid detection. PD signature resistances between 17k and 29k (typically) are detected as valid and reported as Detect Good in the Port Status register. Values outside this range, including open

and short circuits, are also reported. If the port measures less than 1V at the first forced-current test, the detection cycle will abort and Short Circuit will be reported. Table 3 shows the possible detection results.

Table 3. Detection Status

MEASURED PD SIGNATURE	DETECTION RESULT
Incomplete or Not Yet Tested	Detect Status Unknown
$<2.4k$	Short Circuit
Capacitance $> 2.7\mu F$	C_{PD} too High
$2.4k < R_{PD} < 17k$	R_{SIG} too Low
$17k < R_{PD} < 29k$	Detect Good
$>29k$	R_{SIG} too High
$>50k$	Open Circuit
Voltage $> 10V$	Port Voltage Outside Detect Range

Operating Modes

The port's operating mode determines when the LTC4274 runs a detection cycle. In manual mode, the port will idle until the host orders a detect cycle. It will then run detection, report the results, and return to idle to wait for another command.

In semi-auto mode, the LTC4274 autonomously polls the port for PDs, but it will not apply power until commanded to do so by the host. The Port Status register is updated at the end of each detection cycle. If a valid signature resistance is detected and classification is enabled, the port will classify the PD and report that result as well.

Figure 12. PD Detection

APPLICATIONS INFORMATION

The port will then wait for at least 100ms (or 2 seconds if midspan mode is enabled), and will repeat the detection cycle to ensure that the data in the Port Status register is up-to-date.

If the port is in semi-auto mode and high power operation is enabled, the port will not turn on in response to a power-on command unless the current detect result is detect good. Any other detect result will generate a t_{START} fault if a power-on command is received. If the port is not in high power mode, it will ignore the detection result and apply power when commanded, maintaining backwards compatibility with the LTC4259A.

Behavior in AUTO pin mode is similar to semi-auto; however, after Detect Good is reported and the port is classified (if classification is enabled), it is automatically powered on without further intervention. In standalone (AUTO pin) mode, the I_{CUT} and I_{LIM} thresholds are automatically set; see the Reset and the AUTO Pin section for more information.

The signature detection circuitry is disabled when the port is initially powered up with the AUTO pin low, in shutdown mode, or when the corresponding Detect Enable bit is cleared.

Detection of Legacy PDs

Proprietary PDs that predate the original IEEE 802.3af standard are commonly referred to today as legacy devices. One type of legacy PD uses a large common mode capacitance ($>10\mu\text{F}$) as the detection signature. Note that PDs in this range of capacitance are defined as invalid, so a PSE that detects legacy PDs is technically noncompliant with the IEEE spec.

The LTC4274 can be configured to detect this type of legacy PD. Legacy detection is disabled by default, but can be manually enabled. When enabled, the port will report Detect Good when it sees either a valid IEEE PD or a high-capacitance legacy PD. With legacy mode disabled, only valid IEEE PDs will be recognized.

CLASSIFICATION

802.3af Classification

A PD can optionally present a classification signature to the PSE to indicate the maximum power it will draw while operating. The IEEE specification defines this signature as a constant current draw when the PSE port voltage is in the V_{CLASS} range (between 15.5V and 20.5V), with the current level indicating one of 5 possible PD classes. Figure 14 shows a typical PD load line, starting with the slope of the $25\text{k}\Omega$ signature resistor below 10V, then transitioning to the classification signature current (in this case, Class 3) in the V_{CLASS} range. Table 4 shows the possible classification values.

Table 4. Classification Values

CLASS	RESULT
Class 0	No Class Signature Present; Treat Like Class 3
Class 1	3W
Class 2	7W
Class 3	13W
Class 4	25.5W (Type 2)

If classification is enabled, the port will classify the PD immediately after a successful detection cycle in semi-auto or AUTO pin modes, or when commanded to in manual mode. It measures the PD classification signature by applying 18V for 12ms (both values typical) to the port via

Figure 13. PD Classification

APPLICATIONS INFORMATION

the OUT pin and measuring the resulting current; it then reports the discovered class in the Port Status register. If the LTC4274 is in AUTO pin mode, it will additionally use the classification result to set the I_{CUT} and I_{LIM} thresholds. See the Reset and the AUTO/MID Pin section for more information.

The classification circuitry is disabled when the port is initially powered up with the AUTO pin low, in shutdown mode, or when the corresponding Class Enable bit is cleared.

802.3at 2-Event Classification

The 802.3at spec defines two methods of classifying a Type 2 PD.

One method adds extra fields to the Ethernet LLDP data protocol; although the LTC4274 is compatible with this classification method, it cannot perform classification directly since it doesn't have access to the data path. LLDP classification requires the PSE to power the PD as a standard 802.3af (Type 1) device. It then waits for the host to perform LLDP communication with the PD and update the PSE port data. The LTC4274 supports changing the I_{LIM} and I_{CUT} levels on the fly, allowing the host to complete LLDP classification.

The second 802.3at classification method, known as 2-event classification or ping-pong, is fully supported by the LTC4274. A Type 2 PD that is requesting more than 13W will indicate Class 4 during normal 802.3af classification. If the LTC4274 sees Class 4, it forces the port to a specified lower voltage (called the mark voltage, typically 9V), pauses briefly, and then re-runs classification to verify the Class 4 reading (Figure 1). It also sets a bit in the High Power Status register to indicate that it ran the second classification cycle. The second cycle alerts the PD that it is connected to a Type 2 PSE which can supply Type 2 power levels.

2-event ping-pong classification is enabled by setting a bit in the port's High Power Mode register. Note that a ping-pong enabled port only runs the second classification cycle when it detects a Class 4 device; if the first cycle returns

Class 0 to 3, the port assumes it is connected to a Type 1 PD and does not run the second classification cycle.

Invalid Type 2 Class Combinations

The 802.3at spec defines a Type 2 PD class signature as two consecutive Class 4 results; a Class 4 followed by a Class 0-3 is not a valid signature. In AUTO pin mode, the LTC4274 will power a detected PD regardless of the classification results, with one exception: if the PD presents an invalid Type 2 signature (Class 4 followed by Class 0 to 3), the LTC4274 will not provide power and will restart the detection process. To aid in diagnosis, the Port Status register will always report the results of the last class pulse, so an invalid Class 4–Class 2 combination would report a second class pulse was run in the High Power Status register (which implies that the first cycle found Class 4), and Class 2 in the Port Status register.

POWER CONTROL

External MOSFET, Sense R Summary

The primary function of the LTC4274 is to control the delivery of power to the PSE port. It does this by controlling the gate drive voltage of an external power MOSFET while monitoring the current via an external sense resistor and the output voltage at the OUT pin. This circuitry serves to couple the raw V_{EE} input supply to the port in a controlled manner that satisfies the PD's power needs while minimizing power dissipation in the MOSFET and disturbances on the V_{EE} backplane.

The LTC4274 is designed to use 0.25Ω sense resistors to minimize power dissipation. It also supports 0.5Ω sense resistors, which are the default when LTC4258/LTC4259A compatibility is desired.

Inrush Control

Once the command has been given to turn on the port, the LTC4274 ramps up the GATE pin of the port's external MOSFET in a controlled manner. Under normal power-up circumstances, the MOSFET gate will rise until the port

APPLICATIONS INFORMATION

current reaches the inrush current limit level (typically 450mA), at which point the GATE pin will be servoed to maintain the specified I_{INRUSH} current. During this inrush period, a timer (t_{START}) runs. When output charging is complete, the port current will fall and the GATE pin will be allowed to continue rising to fully enhance the MOSFET and minimize its on-resistance. The final V_{GS} is nominally 13V. If the t_{START} timer expires before the inrush period completes, the port will be turned back off and a t_{START} fault reported.

Current Limit

Each LTC4274 port includes two current limiting thresholds (I_{CUT} and I_{LIM}), each with a corresponding timer (t_{CUT} and t_{LIM}). Setting the I_{CUT} and I_{LIM} thresholds depends on several factors: the class of the PD, the voltage of the main supply (V_{EE}), the type of PSE (1 or 2), the sense resistor (0.5Ω or 0.25Ω), the SOA of the MOSFET, and whether or not the system is required to implement class enforcement.

Per the IEEE spec, the LTC4274 will allow the port current to exceed I_{CUT} for a limited period of time before removing power from the port, whereas it will actively control the MOSFET gate drive to keep the port current below I_{LIM} . The port does not take any action to limit the current when only the I_{CUT} threshold is exceeded, but does start the t_{CUT} timer. The t_{LIM} timer starts when the I_{LIM} threshold is exceeded and current limit is active. If the current drops below the I_{CUT} current threshold before its timer expires, the t_{CUT} timer counts back down, but at 1/16 the rate that it counts up. This allows the current limit circuitry to tolerate intermittent overload signals with duty cycles below about 6%; longer duty cycle overloads will turn the port off.

I_{CUT} is typically set to a lower value than I_{LIM} to allow the port to tolerate minor faults without current limiting.

Per the IEEE specification, the LTC4274 will automatically set I_{LIM} to 425mA (shown in bold in Table 5) during inrush at port turn-on, and then switch to the programmed I_{LIM} setting once inrush has completed. To maintain IEEE

compliance, I_{LIM} should be kept at 425mA for all Type 1 PDs, and 850mA if a Type 2 PD is detected. I_{LIM} is automatically reset to 425mA when a port turns off.

Table 5. Example Current Limit Settings

I_{LIM} (mA)	INTERNAL REGISTER SETTING (hex)	
	$R_{SENSE} = 0.5\Omega$	$R_{SENSE} = 0.25\Omega$
53	88

2975		52

I_{LIM} Foldback

The LTC4274 features a two-stage foldback circuit that reduces the port current if the port voltage falls below the normal operating voltage. This keeps MOSFET power dissipation at safe levels for typical 802.3af MOSFETs,

APPLICATIONS INFORMATION

even at extended 802.3af power levels. Current limit and foldback behavior are programmable. Figure 14 shows MOSFET power dissipation with 802.3af-style foldback compared with a typical MOSFET SOA curve; Figure 15 demonstrates how two-stage foldback keeps the FET within its SOA under the same conditions. Table 4 gives examples of recommended I_{LIM} register settings.

The LTC4274 will support current levels well beyond the maximum values in the 802.3af specification. The shaded areas in Table 5 indicate settings that may require a larger external MOSFET, additional heat sinking, or a reduced t_{LIM} setting.

Figure 14. Turn On Currents vs FET Safe Operating Area at 90°C Ambient

Figure 15. LTC4274 Foldback vs FET Safe Operating Area at 90°C Ambient

MOSFET Fault Detection

LTC4274 PSE ports are designed to tolerate significant levels of abuse, but in extreme cases it is possible for the external MOSFET to be damaged. A failed MOSFET may short source to drain, which will make the port appear to be on when it should be off; this condition may also cause the sense resistor to fuse open, turning off the port but causing the LTC4274 SENSE pin to rise to an abnormally high voltage. A failed MOSFET may also short from gate to drain, causing the LTC4274 GATE pin to rise to an abnormally high voltage. The LTC4274 SENSE and GATE pins are designed to tolerate up to 80V faults without damage.

If the LTC4274 sees any of these conditions for more than 180 μ s, it disables all port functionality, reduces the gate drive pull-down current for the port and reports a FET Bad fault. This is typically a permanent fault, but the host can attempt to recover by resetting the port, or by resetting the entire chip if a port reset fails to clear the fault. If the MOSFET is in fact bad, the fault will quickly return, and the port will disable itself again.

An open or missing MOSFET will not trigger a FET Bad fault, but will cause a t_{START} fault if the LTC4274 attempts to turn on the port.

Voltage and Current Readback

The LTC4274 measures the output voltage and current at each port with an internal A/D converter. Port data is only valid when the port power is on. The converter has two modes:

- Slow mode: 14 samples per second, 14.5 bits resolution
- Fast mode: 440 samples per second, 9.5 bits resolution

In fast mode, the least significant 5 bits of the lower byte are zeroes so that bit scaling is the same in both modes.

Disconnect

The LTC4274 monitors the port to make sure that the PD continues to draw the minimum specified current. A disconnect timer counts up whenever port current is below 7.5mA (typ), indicating that the PD has been disconnected. If the t_{DIS} timer expires, the port will be turned off and the disconnect bit in the fault event register will be set. If the current returns before the t_{DIS} timer runs out, the

4274fa

APPLICATIONS INFORMATION

timer resets and will start counting from the beginning if the undercurrent condition returns. As long as the PD exceeds the minimum current level more often than t_{DIS} , it will stay powered.

Although not recommended, the DC disconnect feature can be disabled by clearing the DC Disconnect Enable bit. Note that this defeats the protection mechanisms built into the IEEE spec, since a powered port will stay powered after the PD is removed. If the still-powered port is subsequently connected to a non-PoE data device, the device may be damaged.

The LTC4274 does not include AC disconnect circuitry, but includes an AC disconnect enable bit to maintain compatibility with the LTC4259A. If the AC Disconnect Enable bit is set, DC disconnect will be used.

Shutdown Pin

The LTC4274 includes a hardware \overline{SHDN} pin. When the \overline{SHDN} pin is pulled to DGND, the port will be shut off immediately. The port remains shut down until re-enabled via I²C or a device reset in AUTO pin mode.

Masked Shutdown

The LTC4274 provides a low latency port shedding feature to quickly reduce the system load when required. By allowing a pre-determined set of ports to be turned off, the current on an overloaded main power supply can be reduced rapidly while keeping high priority devices powered. Each port can be configured to high or low priority; all low-priority ports will shut down within 6.5 μ s after the MSD pin is pulled low. If a port is turned off via MSD, the corresponding Detection and Classification Enable bits are cleared, so the port will remain off until the host explicitly re-enables detection.

SERIAL DIGITAL INTERFACE

Overview

The LTC4274 communicates with the host using a standard SMBus/I²C 2-wire interface. The LTC4274 is a slave-only device, and communicates with the host master using the standard SMBus protocols. Interrupts are signaled to

the host via the \overline{INT} pin. The Timing Diagrams (Figures 5 through 9) show typical communication waveforms and their timing relationships. More information about the SMBus data protocols can be found at www.smbus.org.

The LTC4274 requires both the V_{DD} and V_{EE} supply rails to be present for the serial interface to function.

Bus Addressing

The LTC4274's primary serial bus address is 010xxxxb, with the lower four bits set by the AD3-AD0 pins; this allows up to 16 LTC4274s on a single bus. All LTC4274s also respond to the address 0110000b, allowing the host to write the same command (typically configuration commands) to multiple LTC4274s in a single transaction. If the LTC4274 is asserting the \overline{INT} pin, it will also respond to the alert response address (0001100b) per the SMBus spec.

Interrupts and SMBAlert

Most LTC4274 port events can be configured to trigger an interrupt, asserting the \overline{INT} pin and alerting the host to the event. This removes the need for the host to poll the LTC4274, minimizing serial bus traffic and conserving host CPU cycles. Multiple LTC4274s can share a common \overline{INT} line, with the host using the SMBAlert protocol (ARA) to determine which LTC4274 caused an interrupt.

Register Description

For information on serial bus usage and device configuration and status, refer to the LTC4274 Software Programming documentation.

EXTERNAL COMPONENT SELECTION

Power Supplies and Bypassing

The LTC4274 requires two supply voltages to operate. V_{DD} requires 3.3V (nominally) relative to DGND. V_{EE} requires a negative voltage of between -44V and -57V for Type 1 PSEs, or -50V to -57V for Type 2 PSEs, relative to AGND. The relationship between the two grounds is not fixed; AGND can be referenced to any level from V_{DD} to DGND, although it should typically be tied to either V_{DD} or DGND.

APPLICATIONS INFORMATION

V_{DD} provides power for most of the internal LTC4274 circuitry, and draws a maximum of 3mA. A ceramic decoupling cap of at least $0.1\mu\text{F}$ should be placed from V_{DD} to DGND, as close as practical to each LTC4274 chip.

Figure 16 shows a three component low dropout regulator for a negative supply to DGND generated from the negative V_{EE} supply. V_{DD} is tied to AGND and DGND is negative referenced to AGND. This regulator drives a single LTC4274 device. In Figure 17, DGND is tied to AGND in this boost converter circuit for a positive V_{DD} supply of 3.3V above AGND. This circuit can drive multiple LTC4274 devices and opto couplers.

Figure 16. Negative LDO to DGND

V_{EE} is the main supply that provides power to the PD. Because it supplies a relatively large amount of power and is subject to significant current transients, it requires more design care than a simple logic supply. For minimum IR loss and best system efficiency, set V_{EE} near maximum amplitude (57V), leaving enough margin to account for transient over- or undershoot, temperature drift, and the line regulation specs of the particular power supply used.

Bypass capacitance between AGND and V_{EE} is very important for reliable operation. If a short circuit occurs at the output port it can take as long as $1\mu\text{s}$ for the LTC4274 to begin regulating the current. During this time the current is limited only by the small impedances in the circuit and a high current spike typically occurs, causing a voltage transient on the V_{EE} supply and possibly causing the LTC4274 to reset due to a UVLO fault. A $1\mu\text{F}$, 100V X7R capacitor placed near the V_{EE} pin is recommended to minimize spurious resets.

Isolating the Serial Bus

The LTC4274 includes a split SDA pin (SDAIN and SDAOUT) to ease opto-isolation of the bidirectional SDA line.

IEEE 802.3 Ethernet specifications require that network segments (including PoE circuitry) be electrically isolated from the chassis ground of each network interface device. However, network segments are not required to be isolated

Figure 17. Positive V_{DD} Boost Converter

APPLICATIONS INFORMATION

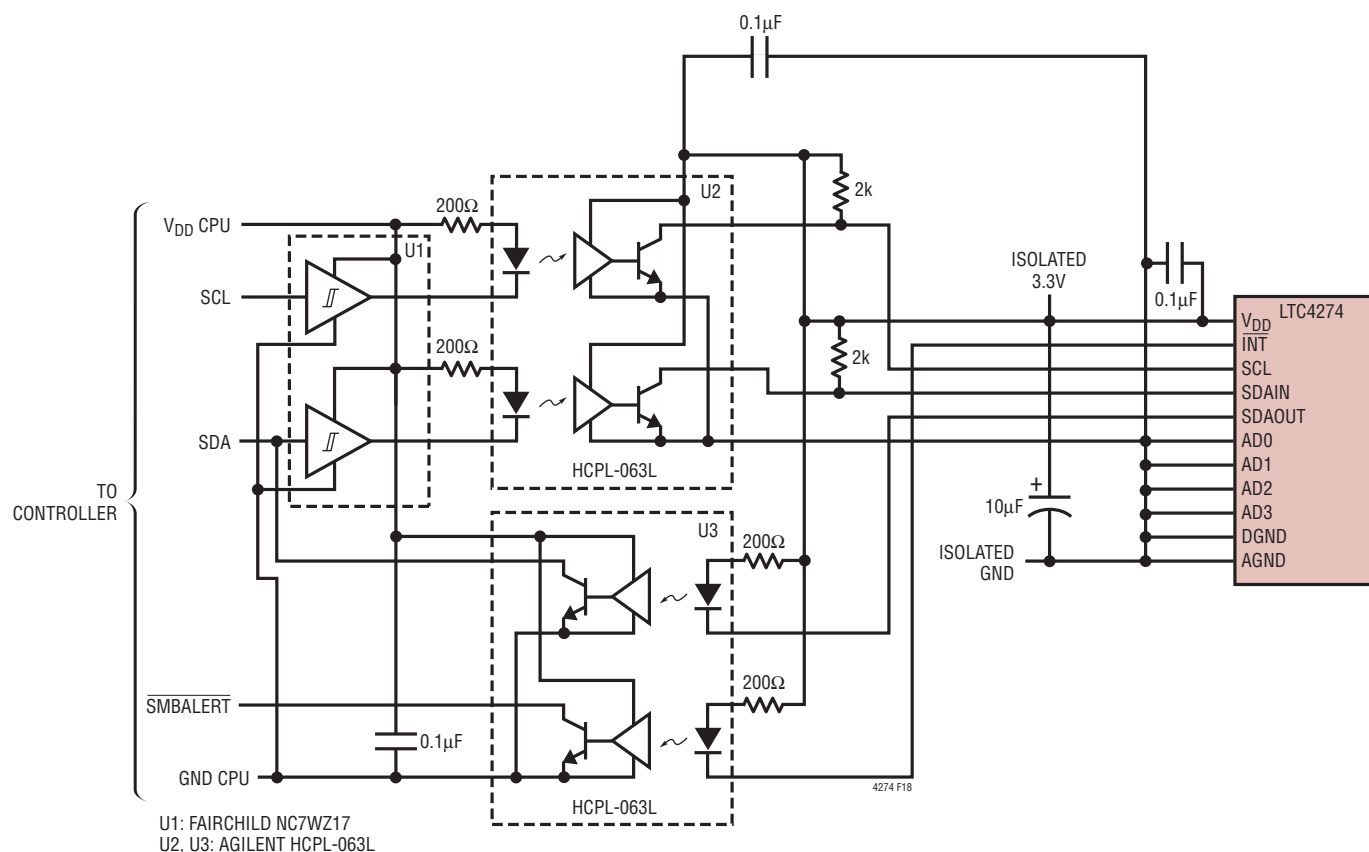

Figure 18. Opto-Isolating the I²C Bus

from each other, provided that the segments are connected to devices residing within a single building on a single power distribution system.

For simple devices such as small PoE switches, the isolation requirement can be met by using an isolated main power supply for the entire device. This strategy can be used if the device has no electrically conducting ports other than twisted-pair Ethernet. In this case, the SDAIN and SDAOUT pins can be tied together and will act as a standard I²C/SMBus SDA pin.

If the device is part of a larger system, contains additional external non-Ethernet ports, or must be referenced to protective ground for some other reason, the Power over Ethernet subsystem (including all LTC4274s) must be electrically isolated from the rest of the system. Figure 18

shows a typical isolated serial interface. The SDAOUT pin of the LTC4274 is designed to drive the inputs of an optocoupler directly. Standard I²C/SMBus devices typically cannot drive opto-couplers, so U1 is used to buffer the signals from the host controller side.

External MOSFET

Careful selection of the power MOSFET is critical to system reliability. LTC recommends either Fairchild IRFM120A, FDT3612, FDMC3612 or Philips PHT6NQ10T for their proven reliability in Type 1 and Type 2 PSE applications. Non-standard applications that provide more current than the 850mA IEEE maximum may require heat sinking and other MOSFET design considerations. Contact LTC Applications before using a MOSFET other than one of these recommended parts.

APPLICATIONS INFORMATION

Sense Resistor

The LTC4274 is designed to use either 0.5Ω or 0.25Ω current sense resistors. For new designs 0.25Ω is recommended to reduce power dissipation; the 0.5Ω option is intended for existing systems where the LTC4274 is used as a drop-in replacement for the LTC4258 or LTC4259A. The lower sense resistor values reduce heat dissipation. Four commonly available 1Ω resistors (0402 or larger package size) can be used in parallel in place of a single 0.25Ω resistor. In order to meet the I_{CUT} and I_{LIM} accuracy required by the IEEE specification, the sense resistors should have $\pm 1\%$ tolerance or better, and no more than $\pm 200\text{ppm}/^\circ\text{C}$ temperature coefficient.

Output Cap

The port requires a $0.22\mu\text{F}$ cap across its output to keep the LTC4274 stable while in current limit during startup or overload. Common ceramic capacitors often have significant voltage coefficients; this means the capacitance is reduced as the applied voltage increases. To minimize this problem, X7R ceramic capacitors rated for at least 100V are recommended.

ESD/Cable Discharge Protection

Ethernet ports can be subject to significant ESD events when long data cables, each potentially charged to thousands of volts, are plugged into the low impedance of the RJ45 jack. To protect against damage, the port requires a pair of clamp diodes; one to AGND and one to V_{EE} (Figure 10). An additional surge suppressor is required for each LTC4274 chip from V_{EE} to AGND. The diodes at the port steer harmful surges into the supply rails, where they are absorbed by the surge suppressor and the V_{EE} bypass capacitance. The surge suppressor has the additional benefit of protecting the LTC4274 from transients on the V_{EE} supply.

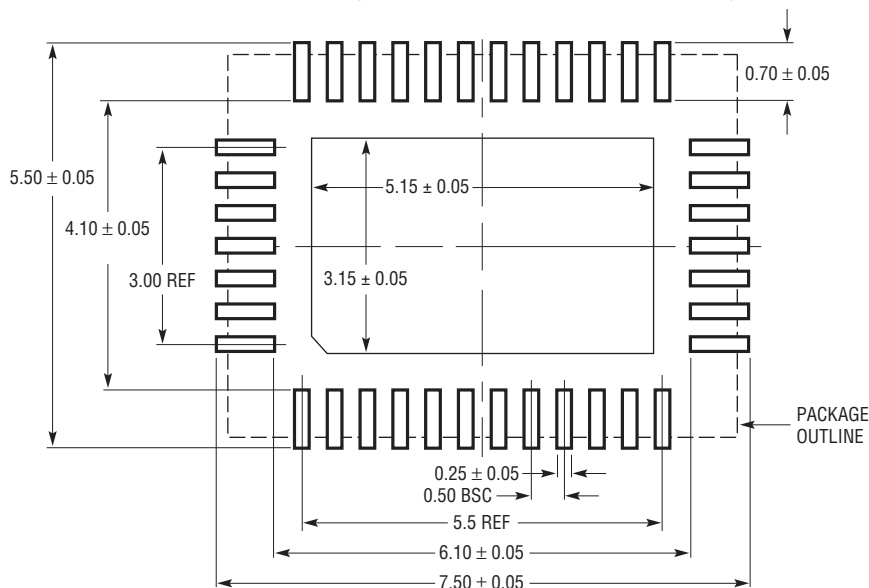

S1B diodes work well as port clamp diodes, and an SMAJ58A or equivalent is recommended for the V_{EE} surge suppressor.

LAYOUT GUIDELINES

Standard power layout guidelines apply to the LTC4274: place the decoupling caps for the V_{DD} and V_{EE} supplies near their respective supply pins, use ground planes, and use wide traces wherever there are significant currents.

PACKAGE DESCRIPTION

UHF Package
38-Lead Plastic QFN (5mm × 7mm)
 (Reference LTC DWG # 05-08-1701 Rev C)

RECOMMENDED SOLDER PAD LAYOUT
 APPLY SOLDER MASK TO AREAS THAT ARE NOT SOLDERED

NOTE:

1. DRAWING CONFORMS TO JEDEC PACKAGE OUTLINE MO-220 VARIATION WHKD
2. DRAWING NOT TO SCALE
3. ALL DIMENSIONS ARE IN MILLIMETERS

4. DIMENSIONS OF EXPOSED PAD ON BOTTOM OF PACKAGE DO NOT INCLUDE MOLD FLASH. MOLD FLASH, IF PRESENT, SHALL NOT EXCEED 0.20mm ON ANY SIDE
5. EXPOSED PAD SHALL BE SOLDER PLATED
6. SHADED AREA IS ONLY A REFERENCE FOR PIN 1 LOCATION ON THE TOP AND BOTTOM OF PACKAGE

REVISION HISTORY

REV	DATE	DESCRIPTION	PAGE NUMBER
A	4/11	Revised entire data sheet	1 to 28
